Major factors in language evolution

- Efficient information transfer
- Learnability

Past research

Cognitive learning biases effect explanatory perturbations in language transmission
(cf. Kirby et al 2007;2014)

But

We expect class of relevant transmission perturbations to be larger

(Iterated) learning with state-noise

The probability that s_a is the actual state when the learner observes s_l is

$$P_N(s_a | s_l) \propto P(s_a) P_N(s_l | s_a)$$

The probability that the teacher observes s_t when the learner observes s_l is

$$P_N(s_t | s_l) = \sum_{s_a} P(s_a | s_l) P_N(s_t | s_a)$$

The probability that type t produces a perceived sequence d_l is

$$P_N(d_l | \tau) = \prod_{\langle s_l, m \rangle \in d_l} \sum_{s_t} P_N(s_t | s_l) P(m | s_t, \tau)$$

The probability that a learner acquires type j when learning from type i is then:

$$P_N(\tau_j \rightarrow \tau_i) \propto \sum_{d \in D_k} P_N(d_l | \tau_j) F(\tau_i | d)$$

Noise

learners consider the posterior probability of τ given a data sequence d of $\langle s, m \rangle$ pairs

$$P(\tau | d) \propto \underbrace{P(\tau)}_{\text{prior}} \underbrace{P(d | \tau)}_{\prod_{\langle s, m \rangle \in d} P(m | s, \tau)}$$

With a parametrized posterior:

$$F(\tau | d) \propto P(\tau | d)^l, \quad l \geq 1$$

The probability that a learner acquires type j when learning from type i is then:

$$P(\tau_j \rightarrow \tau_i) \propto \sum_{d \in D_k} P(d | \tau_j) F(\tau_i | d)$$

Conclusions

- Systematic noise in agents' perception of world states can give rise to stochastic perturbations that may influence and explain language change
- Noisy perception may mimic effects of cognitive biases and offers a neutral alternative to the study of language evolution under functional competition or differential learnability (cf. Real & Griffiths 2009)

Case study I: Vagueness

- Two messages; hundred states
- Probability of perception of actual state as perceived state:

$$P_N(\cdot | s_a) \sim N(s_a, \sigma, 0, 99)$$

- Types:

$$\tau \in [0; 99]$$

- Linguistic behavior:

$$P(m_1 | s, \tau) = \delta_{s \geq \tau} = (1 - P(m_2 | s, \tau))$$

Case study II: Meaning deflation

- One message; hundred states
- Noise signature and type space as in case study I
- We assume learners to take absence of observations into account:

$$P(\tau | d_l) \propto \text{Binom}(\text{successes} = k - |d_l|, \text{trials} = k,$$

$$\text{succ. prob} = \sum_{i=0}^{\tau-1} P(s = i)) \prod_{s \in d_l} P(m | s, \tau)$$

Case study III: Scalar Expressions

- Previous research:
 - widespread adoption of non-upper bounded meaning in weak scalar expressions provided prior that favours them (Brochhagen et al. 2016)
- Target types:

		$\frac{L_{\text{bound}}}{m_{\text{some}} \quad m_{\text{all}}}$	$\frac{L_{\text{lack}}}{m_{\text{some}} \quad m_{\text{all}}}$
<u>Literal</u>	$s_{\forall} \quad s_{\exists \rightarrow \forall}$	$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$	$\begin{pmatrix} 0.5 & 0.5 \\ 1 & 0 \end{pmatrix}$
<u>Pragmatic</u>	$s_{\forall} \quad s_{\exists \rightarrow \forall}$	$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$	$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$

- Linguistic behavior:

$$P(m | s, \tau = \langle \text{lexicon}, \text{use} \rangle)$$

- Noise signature:

$$P(s_{\forall} | s_{\exists \rightarrow \forall}) = \varepsilon$$

$$P(s_{\exists \rightarrow \forall} | s_{\forall}) = \delta$$
